Language Models and the N-gram Model

(Part 1 of Modelling Textual Data Series)

Rey R. Cuenca*

May 2022

Abstract

This paper gives a quick introduction to the language models and the n-gram model.

1 Motivation: Modelling Language Intuition

Any person with the some basic fluency of the English language would find that sentence (A) "sounds more grammatical" than sentence (B).

- (A) The food is already served to the customers.
- (B) *The food served is already to the customers.*

How do they do this? It would be great to mathematized this kind of "grammatical intuition". Doing so would help us build machines (computers) to automate the process of checking the grammaticality of any given sentence and lessen both burden and inaccuracies when doing it manually specially in situations where they are provided in volumes.

In this paper, we introduce the concept of *language models* (LMs) and present one, belonging to this family, called the n-gram model.

2 Notations and Representations

Recall that our goal is to provide a mathematical representation, a *mathematical model* to be exact, of the "grammatical intuition" discussed in the previous section.

^{*}Department of Mathematics and Statistics, MSU-Iligan Institute of Technology

Since we are to translate such abstract idea to mathematical terms, we need to introduce some mathematical notations. First is the representation of sentences.

Notation	Description
w_i	tokens (e.g. words, phrases,)
$\mathbf{w} = (w_1, w_2, \dots, w_n)$	sentences

Example 2.1. Consider the following sentence:

The dog is barking.

We could write this as a vector

$$\mathbf{w} = (\mathsf{The}, \mathsf{dog}, \mathsf{is}, \mathsf{barking})$$

where

Notice, we did not include the period "." symbol. However, depending on the usage case, we may include this as part one of the tokens in sentences or represent it with another notation like in the following example.

Example 2.2. In some cases, it is useful to introduce some auxiliary notations representing the starting and ending of a given sentence like the following.

Writing this in a vector form, we have

$$\mathbf{w} = (\langle s \rangle, \text{The}, \text{dog}, \text{is}, \text{barking}, \langle /s \rangle)$$

where

$$\begin{array}{ccc} i & w_i \\ \hline 1 & \langle \mathtt{s} \rangle \\ 2 & \mathsf{The} \\ 3 & \mathsf{dog} \end{array}$$

3 The Langauge Model

The "grammatical intuition" can essentially be viewed in two ways:

- 1. Given a sentence, identify whether it's grammatical or not.
- 2. Given two sentences, identify which is more grammatically sound.

The mathematical formulation for the first one is equivalent to finding a function f such that given a sentence \mathbf{w} ,

$$f(\mathbf{w}) = \begin{cases} 1 & \mathbf{w} \text{ is grammatical} \\ 0 & \text{otherwise} \end{cases}$$
 (1)

Function f here is an example of what we call a *classifier*. The term comes from the goal of identifying whether an input sentence is grammatical or not using f. Knowing how to construct f is discussed in the second part of this tutorial.

The second one can be regarded as finding a function $P(\cdot)$ that gives a numerical score to a given sentence w of its "degree of grammaticality". That is, the higher the score $P(\mathbf{w})$ the more grammatical it is. Thus, given two sentences \mathbf{w}_1 and \mathbf{w}_2 , we say that \mathbf{w}_1 is more grammatical than \mathbf{w}_2 if and only if

$$P(\mathbf{w}_1) > P(\mathbf{w}_2). \tag{2}$$

If we stipulate some further conditions that P is a probability function, that is,

(1) $P(\mathbf{w}) \ge 0$ for all \mathbf{w} and

(2)
$$\int P(\mathbf{w})d\mathbf{w} = 1$$

then we call P a *language model*. The question now is how do we construct P.

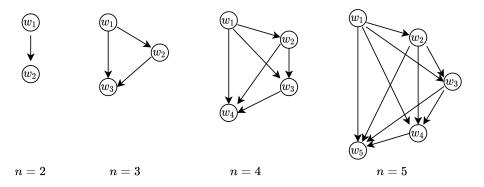

Figure 1: Probabilistic graphical presentation of $P(\mathbf{w})$ for n=2,3,4,5 number of tokens.

4 N-gram Language Model

Since the function P in a language model is defined as a probability function, sentences w are treated as random vectors. Thus, using the product rule of probabilities

$$P(\mathbf{w}) = P(w_1, w_2, \dots, w_n)$$

= $P(w_1)P(w_2|w_1)P(w_3|w_1, w_2) \cdots P(w_n|w_1, w_2, \dots, w_{n-1}).$

If we let $\mathbf{w}_{1:k} := (w_1, \dots, w_k)$, then we can write more compactly the above product as

$$P(\mathbf{w}) = \prod_{k=1}^{n} P(w_k | \mathbf{w}_{1:k-1})$$
(3)

where $(w_r|\mathbf{w}_{u:v}) = w_r$ if u > v.

The question of interest now is "How do we estimate the probabilities?". The simplest way to do this is to resort to *counts*. Let's first add some additional notations in our arsenal.

Notation	Description
$C(w_a)$	number of times the token w_a occurs in the
$C(w_aw_b)$	corpus number of times the sequence of tokens $w_a w_b$ occurs in the corpus
$C(\mathbf{w}_{1:k})$	number of times the sequence of tokens $w_{1:k}$ occurs in the corpus

Example 4.1. Consider the brown corpus data set available for download in Kaggle (Brown Corpus Data, 2018). The full code is presented in Appendix A.

```
tokens_dt
#> Source: local data table [1,208,536 x 3]
#> Call: `_DT2`
#>
#>
        id label
                   token
     <int> <chr>
#>
                    <chr>
#> 1
       1 religion <s>
#> 2
        1 religion furthermore
#> 3 1 religion ,
#> 4 1 religion as
#> 5
        1 religion an
#> 6 1 religion encouragement
#> # ... with 1,208,530 more rows
#> # Use as.data.table()/as.data.frame()/as_tibble() to access results
Now let us consider counting the token w = (in).
tokens dt %>%
  filter(token == "in") %>%
  count(token) %>%
  as_tibble
#> # A tibble: 1 x 2
#>
     token
     <chr> <int>
#> 1 in
           21337
Thus, C(in) = 21, 337.
Now let us try to count the token sequence w = (in, the).
tokens_dt %>%
  mutate(token2 = lead(token, default = "")) %>%
  filter(token == "in" & token2 == "the") %>%
  count(token, token2) %>%
  as_tibble -> count_in_the
count_in_the
#> # A tibble: 1 x 3
     token token2
#>
     <chr> <chr> <int>
```

#> 1 in

the

6025

Thus, C(in) = 6,025.

One can verify using similar code the following counts:

$$C(\texttt{of}, \texttt{the}) = 9,717$$

$$C(to, the) = 3,484$$

$$C(to, be) = 1,718$$

With this *C*-notation we can estimate¹ the probabilities as

$$P(w_k|\mathbf{w}_{1:(k-1)}) = \frac{P(w_k, \mathbf{w}_{1:(k-1)})}{P(\mathbf{w}_{1:(k-1)})} = \frac{P(\mathbf{w}_{1:k})}{P(\mathbf{w}_{1:(k-1)})} = \frac{C(\mathbf{w}_{1:k})}{C(\mathbf{w}_{1:(k-1)})}$$
(4)

However, it would be impractical to apply this formula because almost any long stretch of token sequence rarely occur in a given corpus, i.e., it would result to zero counts. For example, from the given brown corpus above, one can show (See Appendix B) the following count:

$$C(\text{in}, \text{the}, \text{garden}, \text{just}, \text{outside}, \text{city}) = 0$$

With this practical restriction, instead of computing probabilities from past (n-1) token sequences we simply approximate it with the N token neighbors to the left, i.e.,

$$P(w_n|\mathbf{w}_{1:(n-1)}) \approx P(w_n|\mathbf{w}_{(n-N+1):(n-1)}).$$

This simplifies the model given by Eq (3) into

$$P(\mathbf{w}) = \prod_{k=1}^{n} P(w_k | \mathbf{w}_{(k-N+1):(k-1)})$$
 (5)

where $(w_r|\mathbf{w}_{u:v}) = w_r$ if u > v.

Equation (5) is called the *N*-gram model.

• When N = 1, we have a *unigram* and Eq. (5) simplifies to

$$P(\mathbf{w}) = \prod_{k=1}^{n} P(w_k) \tag{6}$$

noting that $P(w_k|\mathbf{w}_{k:(k-1)}) = P(w_k)$.

¹See SNLP p.33.

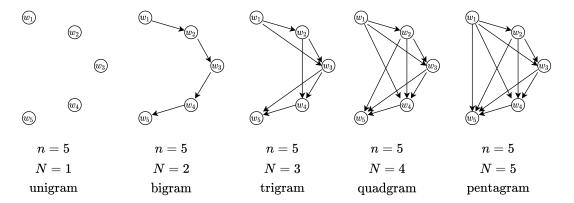

Figure 2: Probabilistic graphical presentation of an N-gram model with n=5 tokens and for N=1,2,3,4,5.

• When N = 2, we have a *bigram* and Eq. (5) simplifies to

$$P(\mathbf{w}) = \prod_{k=1}^{n} P(w_k | w_{k-1})$$
(7)

noting that $P(w_k|\mathbf{w}_{(k-1):(k-1)}) = P(w_k|w_{k-1})$.

• When N = 3, we have a *trigram* and Eq. (5) simplifies to

$$P(\mathbf{w}) = \prod_{k=1}^{n} P(w_k | w_{k-2} w_{k-1})$$
 (8)

noting that $P(w_k|\mathbf{w}_{(k-2):(k-1)}) = P(w_k|w_{k-2}w_{k-1})$.

We can now simplify the probability provided in Eq. (4):

• When N=1,

$$P(w_k) = \frac{C(w_k)}{\sum_{k=1}^{n} C(w_k)}$$
 (9)

• When N=2,

$$P(w_k|w_{k-1}) = \frac{C(w_{k-1}w_k)}{C(w_{k-1})}$$
(10)

• When N=3,

$$P(w_k|w_{k-2}w_{k-1}) = \frac{C(w_{k-2}w_{k-1}w_k)}{C(w_{k-2}w_{k-1})}$$
(11)

Example 4.2 (Brown Corpus Unigram). Let us construct a unigram model from Brown corpus tokens_dt.

```
tokens_dt %>%
  count(token) %>%
  arrange(desc(n)) %>%
  ungroup %>%
  mutate(unigram_prob = n/sum(n)) %>%
  rename(unigram = token) -> unigram_dt

unigram_dt %>%
  as_tibble
```

```
#> # A tibble: 49,780 x 3
#>
                n unigram_prob
     unigram
     <chr> <int>
#>
                         <dbl>
           69971
#> 1 the
                      0.0579
#> 2 ,
             58306
                      0.0482
#> 3 </s> 57340
#> 4 <s> 57340
                      0.0474
                     0.0474
#> 5 of
             36412
                      0.0301
#> 6 and
            28870
                       0.0239
#> 7 to
             26158
                       0.0216
#> 8 a
             23196
                       0.0192
#> 9 in
             21337
                       0.0177
#> 10 that
             10594
                       0.00877
#> # ... with 49,770 more rows
```

Example 4.3 (Brown Corpus Bigram). Let us construct a bigram model from Brown corpus tokens_dt.

```
tokens_dt %>%
  mutate(w2 = lead(token, default = "")) %>%
  filter(token!="</s>" & w2!="<s>") %>%
  count(token, w2) %>%
  arrange(desc(n)) %>%
  ungroup %>%
  group_by(token) %>%
  mutate(bigram_prob = n/sum(n)) %>%
  ungroup %>%
  mutate(bigram = str_c(token,"_",w2)) %>%
  select(bigram,n,bigram_prob) -> bigram_dt

bigram_dt %>%
  as_tibble
```

```
#> # A tibble: 430,392 x 3
```

```
#>
     bigram
                 n bigram_prob
#>
     <chr>
             <int>
                        <dbl>
#> 1 of the
              9717
                        0.267
#> 2 <s> the 6857
                       0.120
#> 3 ,_and
              6300
                       0.108
#> 4 in the
              6025
                       0.282
#> 5 <s>_``
              4168
                       0.0727
#> 6 ,_the
             3783
                       0.0649
#> 7 to_the
              3484
                       0.133
#> 8 <s> he
              2983
                       0.0520
#> 9 on_the
              2466
                        0.366
#> 10 and the 2247
                        0.0778
#> # ... with 430,382 more rows
```

Example 4.4 (Brown Corpus Trigram). Let us construct a trigram model from Brown corpus tokens_dt.

```
tokens_dt %>%
  mutate(w2 = lead(token, default = "")) %>%
  mutate(w3 = lead(w2, default = "")) %>%
  filter((token!="</s>" & w2!="<s>") & (w2!="</s>" & w3!="<s>")) %>%
  count(token, w2, w3) %>%
  arrange(desc(n)) %>%
  ungroup %>%
  group_by(token, w2) %>%
  mutate(trigram_prob = n/sum(n)) %>%
  ungroup %>%
  mutate(trigram = str_c(token,"_",w2,"_",w3)) %>%
  select(trigram,n,trigram_prob) -> trigram_dt

trigram_dt %>%
  as_tibble
```

```
#> # A tibble: 842,641 x 3
#>
     trigram
                            n trigram_prob
#>
     <chr>
                        <int>
                                     <dbl>
#> 1 ,_and_the
                          656
                                     0.104
#> 2 <s> it is
                         586
                                     0.287
#> 3 <s>_it_was
                          562
                                     0.275
#> 4 <s>_``_i
                         435
                                     0.104
#> 5 <s>_in_the
                         434
                                    0.248
#> 6 one of the
                         403
                                    0.574
#> 7 <s>_he_was
                         363
                                    0.122
#> 8 ''_,_he
                         346
                                    0.170
#> 9 the united states
                         336
                                    0.855
```

```
#> 10 ,_however_, 321 0.879
#> # ... with 842,631 more rows
```

Example 4.5 (Sentence Probability). Under unigram, bigram and trigram models, compute the probability of the sentence

```
<s> I want to eat food </s>
```

Note first that we need to normalize the sentence, e.g., convert all to lowercase letters. Thus, we have $\mathbf{w} = (\langle s \rangle, i, \mathsf{want}, \mathsf{to}, \mathsf{eat}, \mathsf{food}, \langle /s \rangle)$.

• Under the unigram model:

```
P(\mathbf{w}) = \prod_{k=1}^6 P(w_k) = P(\langle \mathbf{s} \rangle) P(\mathbf{i}) P(\mathbf{want}) P(\mathbf{to}) P(\mathbf{eat}) P(\mathbf{food}) P(\langle \mathbf{/s} \rangle).
```

```
sen <- "<s> I want to eat food </s>" %>%
   str_split("\\s+") %>%
   unlist %>%
   str_to_lower(.)

unigram_dt %>%
   filter(unigram %in% sen) %>%
   as_tibble -> pu_sen
```

```
#> # A tibble: 7 x 3
  unigram n unigram_prob
#>
    <chr> <int>
#>
                     <dbl>
#> 1 </s> 57340 0.0474
#> 2 <s>
         57340 0.0474
#> 3 to
         26158 0.0216
         5165 0.00427
#> 4 i
          328 0.000271
#> 5 want
#> 6 food
          147
                0.000122
#> 7 eat
           61
                 0.0000505
```

Thus,

```
\begin{split} P(<\mathbf{s}>\ \mathbf{I}\ \text{want to eat food }</\mathbf{s}>)\\ &=P(<\mathbf{s}>)P(\mathbf{i})P(\mathbf{want})P(\mathbf{to})P(\mathbf{eat})P(\mathbf{food})P(</\mathbf{s}>)\\ &=(0.0474)(0.0043)(0.0003)(0.0216)(0.0001)(0.0001)(0.0474)\\ &=3.4697174\times10^{-19}\\ &\approx0 \end{split}
```

The last expression just shows that under the unigram model, finding the sentence <s> I want to eat food </s> from this corpus is almost impossible.

• Using the bigram model:

```
\begin{split} P(\mathbf{w}) &= \prod_{k=1}^{6} P(w_k|w_{k-1}) \\ &= P(<\mathbf{s}>)P(\mathbf{i}|<\mathbf{s}>)P(\mathsf{want}|\mathbf{i})P(\mathsf{to}|\mathsf{want}) \\ &P(\mathsf{eat}|\mathsf{to})P(\mathsf{food}|\mathsf{eat})P(</\mathbf{s}>|\mathsf{food}) \\ &= \frac{C(<\mathbf{s}>)}{N_T} \cdot \frac{C(<\mathbf{s}>,\mathbf{i})}{C(<\mathbf{s}>)} \cdot \frac{C(\mathbf{i},\mathsf{want})}{C(\mathbf{i})} \cdot \frac{C(\mathsf{want},\mathsf{to})}{C(\mathsf{want})} \\ &\frac{C(\mathsf{to},\mathsf{eat})}{C(\mathsf{to})} \cdot \frac{C(\mathsf{eat},\mathsf{food})}{C(\mathsf{eat})} \cdot \frac{C(\mathsf{food},</\mathbf{s}>)}{C(\mathsf{food})} \\ &= (0.0474458)(0.02397976979421)(0.010648596321394) \\ &\qquad (0.496951219512195)(0.000879272115605169)(0.122448979591837) \\ &= 6.4822787 \times 10^{-10} \end{split}
```

where $P(\langle s \rangle)$ is computed as follows

```
unigram_dt %>%
  filter(unigram == "<s>") %>%
  as_tibble
```

while $P(w_k|w_{k-1})$ are computed as follows.

Observe that the probability $(6.4822787 \times 10^{-10})$ under the bigram model is quite higher by a factor of 1.868244×10^9 compared to that computed under the unigram.

• Using the trigram model:

$$\begin{split} P(\mathbf{w}) &= \prod_{k=1}^{6} P(w_k|w_{k-1}) \\ &= P(\langle \mathbf{s} \rangle) P(\mathbf{i}|\langle \mathbf{s} \rangle) P(\mathbf{want}|\langle \mathbf{s} \rangle, \mathbf{i}) P(\mathbf{to}|\mathbf{i}, \mathbf{want}) \\ &\quad P(\mathbf{eat}|\mathbf{want}, \mathbf{to}) P(\mathbf{food}|\mathbf{to}, \mathbf{eat}) P(\langle /\mathbf{s} \rangle|\mathbf{eat}, \mathbf{food}). \end{split}$$

However, there's a problem. We don't have counts for the trigrams want_to_eat, to_eat_food, and eat_food_</s>. As shown by the following code:

```
#> # A tibble: 0 x 3
#> # ... with 3 variables: trigram <chr>, n <int>, trigram_prob <dbl>
```

This is a typical example of the practical restrictions that the longer the token sequence that rare it is to find the corpus. Computing probabilities is such cases will be answered in the lesson about *smoothing*.

Example 4.6. Suppose we want to know what is the most likely next word of the token sequence

This problem is equivalent to finding w^* where

$$w^* = \underset{w}{\operatorname{arg\,max}} P(w|\mathtt{on},\mathtt{the})$$

Using the estimates for the trigram:

$$w^* = \underset{w}{\operatorname{arg\,max}} \frac{C(\mathtt{on},\,\mathtt{the},\,w)}{C(\mathtt{on},\,\mathtt{the})} = \underset{w}{\operatorname{arg\,max}} C(\mathtt{on},\,\mathtt{the},\,w)$$

where the second equality follows since the denominator does not depend on w. Implementing the counting R, we have

```
trigram_dt %>%
  filter(str_detect(trigram, "^on_the_")) %>%
  arrange(desc(trigram_prob)) -> prob_on_the

prob_on_the %>%
  as_tibble
```

```
#> # A tibble: 1,262 x 3
            n trigram_prob 
<int> <dbl>
#>
      trigram
#>
     <chr>
                     99
#> 1 on_the_other
                                0.0401
                   57
28
#> 2 on_the_basis
                                0.0231
#> 3 on_the_floor
                                0.0114
#> 4 on_the_ground 27
#> 5 on_the_part 26
                                0.0109
                                0.0105
#> 6 on the same
                      22

```

From the results above, we find that the most likely word that follows is $w^* =$ other with $C(\mathtt{on}, \mathtt{the}, w^*) = 99$ or, in terms of probability,

$$P(w^*|\text{on,the}) = 0.040146.$$

5 Generating Random Sentences

With the given N-gram model P, we can generate, i.e. sample, sequence of tokens w.

5.1 Unigram Sentence Generation

For unigram models, we use the following algorithm to generate a sentence:

- 1. Set $w_1 = \langle s \rangle$.
- 2. Generate $U \sim \mathsf{Unif}(0,1)$.
- 3. If $\sum_{k=1}^{i-1} P(w_k) < U \leq \sum_{k=1}^{i} P(w_k)$, then set $w = w_i$ as the next token in the sequence.
- 4. While $w_i \neq </s>$, repeat steps 2 and 3.

Let us now try illustrating this algorithm using the unigram model obtained from the Brown Corpus above. Since we assign $w_1 = \langle s \rangle$ with probability 1, we need to calibrate the probabilites as follows

```
unigram_dt %>%
  filter(unigram!="<s>") %>%
  mutate(unigram_prob = n/sum(n)) -> n_unigram_dt

n_unigram_dt %>%
  as_tibble
```

```
#> # A tibble: 49,779 x 3
     unigram n unigram_prob
     <chr> <int>
#>
                        <dbl>
#> 1 the 69971
                    0.0608
           58306
#> 2 ,
                     0.0506
#> 3 </s> 57340
#> 4 of 36412
                    0.0498
0.0316
#> 5 and
           28870
                    0.0251
#> 6 to
           26158
                    0.0227
                   0.0201
          23196
#> 7 a
#> 8 in
           21337
#> 9 that
           10594
                      0.00920
#> 10 is
            10109
                      0.00878
#> # ... with 49,769 more rows
```

Next, we need to form new columns for $\sum_{k=1}^{i-1} P(w_k)$ and $\sum_{k=1}^{i} P(w_k)$.

```
n_unigram_dt %>%
  filter(unigram != "<s>") %>%
  mutate(P = cumsum(unigram_prob)) %>%
  mutate(LP = lag(P, default = 0)) -> Punigram
```

We now initialize our sentence vector with $w_1 = \langle s \rangle$ and start the loop as stated in Steps 2 to 4:

```
set.seed(11)
sen_gen <- "<s>"
repeat {
    U <- runif(1)
    Punigram %>%
      filter(LP < U & U <= P) %>%
      pull(unigram) -> w
    if (w != "</s>"){
```

```
sen gen <- str c(sen gen, " ", w)
    print(sen gen)
  } else {
    sen_gen <- str_c(sen_gen," ",w)</pre>
    break
  }
}
#> [1] "<s> in"
#> [1] "<s> in the"
#> [1] "<s> in the first"
#> [1] "<s> in the first the"
#> [1] "<s> in the first the ,"
\# [1] "<s> in the first the , nonmetallic"
#> [1] "<s> in the first the , nonmetallic ,"
\# [1] \# in the first the , nonmetallic , is
\# [1] \# in the first the , nonmetallic , is fellows
sen_gen
```

#> [1] "<s> in the first the , nonmetallic , is fellows </s>"

5.2 Bigram Sentence Generation

```
bigram_dt %>%
  separate(bigram,c("w1","w2"), sep="_", remove = FALSE) %>%
  group_by(w1) %>%
  arrange(desc(w1)) %>%
  mutate(P = cumsum(bigram_prob)) %>%
  mutate(LP= lag(P, default = 0)) %>%
  ungroup -> Pbigram

Pbigram %>%
  as_tibble
```

```
#> # A tibble: 430,392 x 7
#>
      bigram
                         n bigram_prob w1
                                                    w2
                                                                   P
                                                                        LP
      <chr>
                     <int>
                                 <dbl> <chr>
                                                    <chr>
                                                               <dbl> <dbl>
#> 1 {0,t}_,
                       1
                                   1
                                        {0,t}
                                                                 1
                                                                        0
#> 2 zworykin_,
                                                                 0.5
                         1

Appendix A

The following is the R code deriving the tokens_dt data table.

```
suppressWarnings(
  suppressMessages(
    library(tidyverse)
    )
  )
tokens_dt <- dtplyr::lazy_dt(</pre>
  read.csv(
   file = "data/brown-corpus/brown.csv",
    header = TRUE
    )
  ) %>%
  select(tokenized text, label) %>%
  mutate(id = seq_along(label)) %>%
  mutate(
    token = str c("<s> ", tokenized text, " </s>") %>%
           str_replace("[ [:punct:]]+ </s>$", " </s>") %>%
           str_to_lower %>%
           str_split("\\s+")
      %>%
  select(id, label, token) %>%
  as_tibble %>%
  unnest(token) %>%
  dtplyr::lazy_dt(.)
```

Appendix B

The following code computes the count:

```
C(\text{in}, \text{the}, \text{garden}, \text{just}, \text{outside}, \text{city}) = 0
```

```
tokens_dt %>%
  mutate(token2 = lead(token, default = "")) %>%
  mutate(token3 = lead(token2, default = "")) %>%
  mutate(token4 = lead(token3, default = "")) %>%
  mutate(token5 = lead(token4, default = "")) %>%
  mutate(token6 = lead(token5, default = "")) %>%
```
